Soymilk is a traditional food in East Asia, and different soybean cultivars lead to different processing characteristics of soymilk. Aimed at establishing the evaluation method to identify the adaptability of different soybean cultivars in soymilk processing, 67 soybean cultivars from different areas in China were chosen in this research to analyse the chemical components and study the processing characteristics of soymilk. The main results show that soymilk made from soybeans with a higher content of protein has a higher yield and viscosity; while soymilk made from soybeans with a lower content of fat and oleinic acid has a higher viscosity. The components and content of fatty acids have a great effect on soymilk flavour, and a higher content of unsaturated fatty acids, including linoleic acid and linolenic acid, which leads to a higher beany flavour compound including hexanal and trans-2-hexenal. Therefore, the beany flavour including hay, lipid oxidation and cereal flavour is greater in sensory evaluation. On the other hand, the OAV value of soymilk is significantly related to the content of fatty acids of different soybean cultivars.

Based on clustering and discriminatory analyses in SPSS, soybean cultivars can be divided into three classes according to their rheological characteristics. Class I: the soymilk has a higher yield and lower viscosity; Class II: the soymilk has a lower yield and higher viscosity; and the remaining soybean cultivars compose the third class. Soybean cultivars can also be classified according to flavour. Class I: the soymilk has a heavy beany flavour and non-beany flavour; Class II: the soymilk has a heavy non-beany flavour and weak beany flavour; Class III: the soymilk has a weak beany flavour and non-beany flavour. Accordingly, an effective evaluation method has been established to identify the adaptability of different soybean cultivars in soymilk processing by means of analysing the chemical components of soybean in this research.
Analysis of Soymilk Processing Characteristics of Different Soybean Cultivars and Establishment of Evaluation Method of Soybean Cultivars Suitable for Soymilk Processing

*P<0.05, **P<0.01

*The higher the content of soluble protein is and the lower the contents of fat and oleic acid are, the relatively higher the viscosity of soymilk will be.*
LOX can catalyze the conversion of polyunsaturated fatty acids like linoleic acid and linolenic acid to hydroperoxides and form micromolecular compounds, such as aldehydes, ketones and alcohols.

The flavor compounds of soymilk are attributed to soybean lipoxygenases (LOX).
Non-beany flavor compounds are formed during the heating of soymilk (Lv, J. Food Sci, 2010).
Research results

**Fatty Acid**
- **Range of the content:**
  - stearic acid: 1.25%~9.19%
  - palmitic acid: 7.91%~22.10%
  - oleic acid: 15.27%~42.29%
  - linoleic acid: 29.95%~70.20%
  - linolenic acid: 2.36%~14.86%

**LOX Activity**
- **Range of the content:**
  - 27.33 ~172.69 U/mg

Research results

Flavor

- Saturated fatty acids can hardly react with LOX, so if the content of saturated fatty acids is high, the concentration of soymilk flavor will be relatively low. Accordingly, if the content of unsaturated fatty acids is high, the concentration of soymilk flavor will be relatively high.

- In sensory evaluation, the soybean cultivars, which have high content of fat, unsaturated fatty acids and low content of saturated fatty acids, have the relatively heavy beany flavor, hay flavor, oil-oxidation flavor and grain flavor.
Research results

Clustering analysis and Discriminant analysis

- The objects that have the similar properties can be divided and classified.
- Data can be sorted into several classes.
- In the same class, the data have a high similarity, while the data in the different classes have a relatively greater difference.

- According to the properties of objects in the known classes, the unknown objects can be estimated and classified into the known classes.

67 kinds of soybean cultivars were classified by the clustering analysis and discriminant analysis.
Figure 1 clustering analysis and discriminant analysis by Statistical Product and Service Solutions (SPSS)
Evaluation of processing quality

Class I: the soymilk has a higher yield and lower viscosity;
Class II: the soymilk has a lower yield and higher viscosity;
The remaining soybean cultivars compose the third class.

The elementary indexes are the content of protein, P, fat and Ca
The data which contain elementary indexes, yield and viscosity are standardized and classified by clustering analysis, and discriminant analysis is used to examine the result.
Class I’: the soymilk has a heavy beany flavor and non-beany flavor;
Class II’: the soymilk has a heavy non-beany flavor and weak beany flavor;
Class III’: the soymilk has a weak beany flavor and non-beany flavor.

Conclusion

- In this study, the yield, viscosity and flavor of soymilk prepared by different soybean cultivars were measured, and the correlations of soybean components and the three aspects were analyzed respectively.
- According to the clustering analysis and discriminant analysis, the soymilk was classified into three classes.
- The fatty acids of soybean cultivars which can produce relatively good soymilk flavor (Class II’) were analyzed, and the content range of each fatty acid was determined. However, we still have to verify and confirm these results.
- It is still a part of the whole research for the establishment of evaluation method of soybean cultivars suitable for the soymilk processing.
Thank you!
